

Chaospy:

A modular implementation of Polynomial Chaos expansions and Monte Carlo methods

Simen Tennøe

Supervisors:

Jonathan Feinberg

Hans Petter Langtangen

Gaute Einevoll

Geir Halmes

University of Oslo, CINPLA

Chaospy is a Python toolbox for forward model UQ

Properties of Chaospy

Monte Carlo methods

$$\sum_{n=0}^N c_n(x) P_n(q)$$

Polynomial Chaos

What is new in Chaospy

**Chaospy is modular and
therefore very flexible**

**Chaospy has support for
dependent variables**

**Chaospy has a large collection
of methods and distributions**

**It is easy to compare different
methods on given a problem**

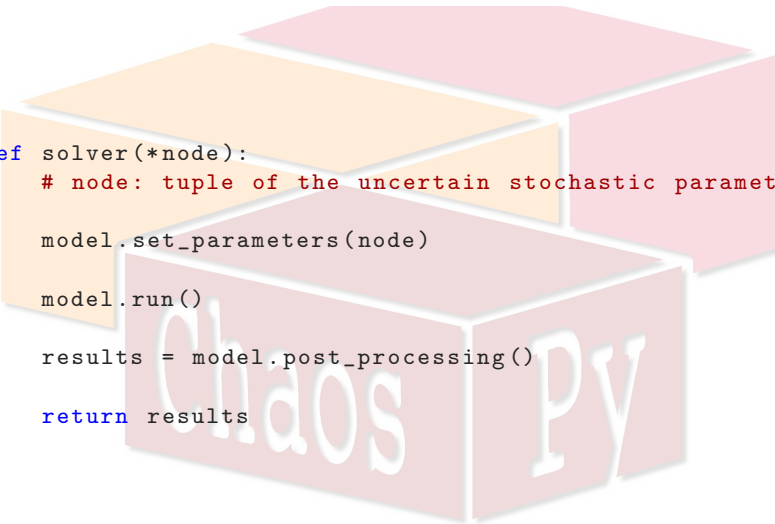

Comparing Chaospy with Turns and Dakota

Feature	Dakota	Turns	Chaospy
Distributions	11	26	64
Copulas	1	7	6
Sampling schemes	4	7.5	7
Orthogonal polynomial schemes	4	3	5
Numerical integration strategies	7	0	7
Regression methods	5	4	8
Analytical metrics	6	6	7

Chaospy has support for many different methods

- ▶ Monte Carlo with variance reduction techniques
- ▶ Intrusive and non-intrusive polynomial chaos
 - ▶ Pseudo-spectral method
 - ▶ Point collocation/regression

All Chaospy needs is a Python wrapper around the forward model

```
def solver(*node):  
    # node: tuple of the uncertain stochastic parameters  
  
    model.set_parameters(node)  
  
    model.run()  
  
    results = model.post_processing()  
  
    return results
```

Chaospy is a completely generic software; for simplicity we use a very simple example problem

$$\frac{du(x)}{dx} = -au(x), \quad u(0) = I.$$

u The quantity of interest.

x Spatial location.

a, I Parameters containing uncertainties.

$$a \sim \text{Uniform}(0, 0.1)$$

$$I \sim \text{Uniform}(8, 10)$$

We want to compute $E(u)$ and $\text{Var}(u)$.

Monte Carlo integration can be used for any model

Monte Carlo with Chaospy

```
import chaospy as cp
import numpy as np

dist_a = cp.Uniform(0, 0.1)
dist_I = cp.Uniform(8, 10)

# Joint distribution
dist = cp.J(dist_a, dist_I)

samples = dist.sample(size=1000)

# solver returns the u(x), where x is fixed
samples_u = [solver(a, I) for a, I in samples]

# solver_u : list of all u values for each
#            set of uncertain parameters

E = np.mean(samples_u, 0)
Var = np.var(samples_u, 0)
```

Convergence of Monte Carlo is slow

$$\varepsilon_E = \int |E(u) - E(\hat{u})| dx$$

$$\varepsilon_{Var} = \int |\text{Var}(u) - \text{Var}(\hat{u})| dx$$

Chaospy has several variance reduction techniques for sampling a distribution

Hammersley sampling:

```
nodes = dist.sample(100, "M")
```

Latin Hypercube sampling:

```
nodes = dist.sample(100, "L")
```

Halton sampling

```
nodes = dist.sample(100, "H")
```

Sobol sampling

```
nodes = dist.sample(100, "S")
```

The different sampling schemes available in Chaospy compared to Turns and Dakota

	Dakota	Turns	Chaospy
Quasi-Monte Carlo scheme			
Faure sequence	No	Yes	No
Halton sequence	Yes	Yes	Yes
Hammersley sequence	Yes	Yes	Yes
Haselgrove sequence	No	Yes	No
Korobov lattice	No	No	Yes
Niederreiter sequence	No	Yes	No
Sobol sequence	No	Yes	Yes
Other methods			
Antithetic variables	No	No	Yes
Importance sampling	Yes	Yes	Yes
Latin Hypercube sampling	Yes	Limited	Yes

Quasi-Monte Carlo with Latin Hypercube sampling

```
import chaospy as cp
import numpy as np

dist_a = cp.Uniform(0, 0.1)
dist_I = cp.Uniform(8, 10)
dist = cp.J(dist_a, dist_I)

samples = dist.sample(size=1000, rule="L")

samples_u = [solver(a, I) for a, I in samples]

E = np.mean(samples_u, 0)
Var = np.var(samples_u, 0)
```

Convergence of quasi-Monte Carlo is better than Monte Carlo, but still slow

Mapping in probability space; the idea behind Polynomial Chaos (PC) theory is to approximate our forward model with a polynomial

$$u(x; q) \approx \hat{u}_M(x; q) = \sum_{n=0}^N \underbrace{c_n(x)}_{\text{Coefficient}} \underbrace{P_n(q)}_{\text{Polynomial}}$$

$\hat{u}_M(x; q)$ is the mapping from the uncertain variables q to the response variable u , x is a set variable.

Mean and variance are calculated from $\hat{u}_M(x; q)$.

P_n are orthogonal polynomials and are generally calculated through the three-term discretized Stiltjes recursion

```
dist = cp.Normal()
P = cp.orth_ttr(3, dist)
print P
[1.0, q0, q0^2-1.0, q0^3-3.0q0]
```

Chaos

Py

Methods for generating expansions of orthogonal polynomials

Orthogonalization Method	Dakota	Turns	Chaospy
Askey–Wilson scheme	Yes	Yes	Yes
Bertran recursion	No	No	Yes
Cholesky decomposition	No	No	Yes
Discretized Stieltjes	Yes	No	Yes
Modified Chebyshev	Yes	Yes	No
Modified Gram–Schmidt	Yes	Yes	Yes

The pseudo-spectral method, used to calculate c_n , needs numerical integration, which demands generating quadrature nodes and weights

```
dist = cp.Normal()

nodes, weights = cp.generate_quadrature(2, dist, rule="G")

print nodes
[[-1.73205081  0.          1.73205081]]
print weights
[ 0.16666667  0.66666667  0.16666667]
```

Numerical integration strategies implemented in the three software toolboxes

Node and weight generators	Dakota	Turns	Chaospy
Clenshaw-Curtis quadrature	Yes	No	Yes
Cubature rules	Yes	No	No
Gauss-Legendre quadrature	Yes	No	Yes
Gauss-Patterson quadrature	Yes	No	Yes
Genz-Keister quadrature	Yes	No	Yes
Leja quadrature	No	No	Yes
Monte Carlo integration	Yes	No	Yes
Optimal Gaussian quadrature	Yes	No	Yes

One slide is enough for the full implementation with the pseudo-spectral method in Chaospy

```
dist_a = cp.Uniform(0, 0.1)
dist_I = cp.Uniform(8, 10)
dist = cp.J(dist_a, dist_I)

P = cp.orth_ttr(2, dist)

nodes, weights = cp.generate_quadrature(3, dist)

samples_u = [solver(*node) for node in nodes.T]

u_hat = cp.fit_quadrature(P, nodes, weights, samples_u,
                          rule="Gaussian")

mean = cp.E(u_hat, dist)
var = cp.Var(u_hat, dist)
```

Convergence of polynomial chaos is much faster than the Monte Carlo methods

Chaospy is an ideal tool for research in UQ for the statistics expert

With a few lines of Python code it is easy to customize:

- ▶ distributions
- ▶ polynomials
- ▶ integration schemes
- ▶ sampling schemes
- ▶ statistical analysis of the result

Custom polynomials:

```
q0, q1 = cp.variable(2)
phi = cp.Poly([1, q0, q1, q0**2 - 1, q0*q1])

print phi
[1, q0, q1, q0^2-1, q0q1]
```

Chaospy handles Polynomial Chaos expansions with stochastically dependent variables

Diffusion in layered media with uncertain boundary, l , and uncertain diffusion constants, D_0 , D_1 .

Uncertain l slows down convergence, but introduction of auxiliary *dependent* variables restores convergence.

Summary: Chaospy is a Python toolbox for forward model UQ with advanced Monte Carlo methods and Polynomial Chaos expansions

Chaospy is modular, flexible,
with syntax that resembles
the mathematics

A vast collection of methods,
ideal for method comparisons

Summary: Chaospy is a Python toolbox for forward model UQ with advanced Monte Carlo methods and Polynomial Chaos expansions
